**HW2:**

**(a)  $p_A=0.7$ ,  $p_a=0.3$ ,  $p_{AA}=0.6$ ,  $p_{aa}=0.01$ ,  $p_{Aa}=0.39$**

**Find probability that the population of size 100 is in HWE.**

$$p_A=0.7$$

$$p_a=0.3$$

$$p_{AA}=0.6$$

$$p_{aa}=0.01$$

$$p_{Aa}=0.39$$

Hardy-Weinberg Equation:

$$p^2 + 2pq + q^2 = 1$$

$$p + q = 1$$

$$p_{AA} = 0.6 \Rightarrow \text{numbers of AA genotype is 60}$$

$$p_{Aa} = 0.39 \Rightarrow \text{numbers of Aa genotype is 39}$$

$$p_{aa} = 0.01 \Rightarrow \text{numbers of aa genotype is 1}$$

Numbers of AA genotype = 60  $\Rightarrow$  total of 120 in population.

Numbers of Aa genotype = 39

Numbers of A alleles = 120 + 39 = 159

Numbers of aa genotype = 1 => total of 2 in population.

Numbers of Aa genotype = 39

Numbers of a alleles = 2 + 39 = 41

The total numbers = 120 + 2 + 39\*2 = 200

We have **dominant allele** and **recessive allele**

**dominant allele =  $p_A = 159/200 = 0.795 \approx 0.7$**

**recessive allele =  $p_a = 41/200 = 0.205 \approx 0.3$**

Quick Check =>  $p+q = 1 \Rightarrow 0.795 + 0.205 = 1$

$p = P_A = 0.795 \Rightarrow p_{AA} = 0.632025$

$p = p_A \approx 0.7 \Rightarrow p_{AA} = 0.49$

$q = p_a = 0.205 \Rightarrow p_{aa} = 0.042025$

$q = p_a \approx 0.3 \Rightarrow p_{aa} = 0.09$

$2*p*q = P_{Aa} = 2*0.632025 * 0.042025 = 0.05312170125$

$P_{aA} = 0.42$

**At first we consider it  $p_{AA} = 0.6$ ,  $p_{aa} = 0.01$  and  $p_{Aa} = 0.39$ . The genotype should be  $p_{AA} = 0.49$ ,  $p_{aa} = 0.9$  and  $p_{Aa} = 0.49$  if the population size 100 is In Hardy-Weinberg.**

**The X test (HW Chi Squared)**

Population
$P^2 * \text{Total} = 0.49 * 100 = 49$
$2 * p * q * \text{Total} = 0.42 * 100 = 42$

$q^2 \cdot \text{Total} = 0.09 \cdot 100 = 9$
---

$$\chi^2 = \sum (\text{observed} - \text{expected})^2 / (\text{expected})$$

$$\chi^2 = (60-49)^2/49 + (1-9)^2/9 + (39-42)^2/42 = 2.469 + 7.111 + 0.214 = \mathbf{9.794}$$

$$\text{Degree of freedom} = n-1 = 2-1 = 1$$

$$\chi^2 = \mathbf{9.794}$$

**Pr ( $\chi^2 > 9.794$ ) = 0.001751 which is less than 0.05 so it is not accepted.**

**b) Given genotype population: AA=100, Aa=50, aa=50. Based on allele frequencies and assuming HWE, What is the expected genotype frequencies?**

**Perform  $\chi^2$  test – do you accept hypothesis that the population is in HWE?**

Numbers of AA genotype = 199 => total of 200 in population.

Numbers of Aa genotype = 50

Numbers of A alleles =  $200 + 50 = 250$

Numbers of aa genotype = 50 => total of 100 in population.

Numbers of Aa genotype = 50

Numbers of a alleles =  $2 + 39 = 150$

The total numbers =  $200 + 100 + 50 \times 2 = 400$

We have **dominant allele** and **recessive allele**

**dominant allele =  $p_A = 250/400 = 0.625$**

**recessive allele =  $p_a = 150/400 = 0.375$**

**The genotype frequencies are:**

AA ( $0.625 \times 0.625 = 0.390625$ )	Aa ( $0.625 \times 0.375 = 0.234375$ )	aa ( $0.375 \times 0.375 = 0.140625$ )
--	--	--

**The genotype should be  $p_{AA} = 0.390625$ ,  $p_{aa} = 0.140625$  and  $p_{Aa} = 0.234375$  In Hardy-Weinberg.**

**The X test (HW Chi Squared)**

$P = 0.625$

$q = 0.375$

<b>Population</b>
-------------------

$P^2 \cdot \text{Total} = 0.390625 \cdot 200 = 78.125$
$2 \cdot p \cdot q \cdot \text{Total} = 2 \cdot 0.625 \cdot 0.375 \cdot 200 = 93.75$
$q^2 \cdot \text{Total} = 0.140625 \cdot 200 = 28.125$

$$\chi^2 = \sum (\text{observed} - \text{expected})^2 - (\text{expected})$$

$$\chi^2 = (100 - 78.125)^2 / 78.125 + (50 - 93.75)^2 / 93.75 + (50 - 28.125)^2 / 28.125 = 6.125 + 20.416 + 17.013 = \mathbf{43.554}$$

$$\text{Degree of freedom} = n - 1 = 2 - 1 = 1$$

$$\chi^2 = \mathbf{43.554}$$

$\Pr(\chi^2 > 43.554) = 0.00001$  which is less than 0.05 so it is not accepted.
